47

48 [Abstract](#)

49 Humans evolved as socially collaborative builders, cooperatively reshaping nature for shelter, creating  
50 villages and towns through collective social engagement. This behavior, identified as niche-construction  
51 [1], enable humans to cooperatively shape the earth into an ecosystem of millions of inter-linked built  
52 environments. As a result, the design and construction industry generate 3% of global GDP [2]; however,  
53 it is a sector in which its productivity improvement output lags when measured against other sectors.  
54 Production in the manufacturing, retail, and agriculture sectors has grown by 500% since 1945, while  
55 output in the construction industry has increased by less than 2% [3]. It is an industry plagued with  
56 system failures, including schedule delays, budget and cost overruns, and contractual disputes. Almost  
57 80% of large projects experience cost overruns of more than 30% and schedule delays of 40% [4]. If the  
58 human need to build is genetically embedded within humans as builders, why is the design and  
59 construction industry so troubled? We argue that the industry's failures are a result of misapplied  
60 project controls, proposing that traditional controls fail to support the front-line builders, who, in  
61 addition to actively building the project, are also fulfilling their evolutionary needs as human niche-  
62 constructors. We argue that this behavior is driven by communal and adaptive social task-level planning,  
63 represented through emergent agent collaboration which is hindered by traditional project controls. As  
64 a result, the adaptive agent-systems conflict with the established systems, reinforcing the inefficiency  
65 and failures that plague the industry. In the following two case studies, we examine and measure the  
66 effects of controls for project change management and how they impact the overall controls systems for  
67 projects and the entire design and construction industry. We propose changes for these systems that  
68 will improve efficiency and productivity on projects and in the industry and recognize and leverage the  
69 role of design and construction teams as niche-constructors, fulfilling their evolutionary need to build.

Using Time and Material (T&M) to Develop and Guide Holons in a Design and Construction Project -  
The results of Two Case Studies.  
Cliff Moser

70 Introduction.

71 Humans create-built environments. Like most living things, humans are niche-constructors [5], shaping  
72 the planet to meet their needs. However, unlike other animals, humans combine and specialize their  
73 abilities, leveraging individual and group expertise and experience. As niche-constructors, humans  
74 collaboratively created agriculture, domesticated animals, constructed cities, and developed social  
75 market economies to establish and support built-environments, reshaping the earth's ecosystems to  
76 meet their needs.

77 In the process, humans create and inhabit complex systems. The modern design and construction  
78 industry is a human-created complex system. It is top-down and market-driven, supporting the capital-  
79 intensive and risk needs of thousands of project-based organizations [6], which plan, design, and build  
80 construction projects. It is a global industry that includes the design professions of architecture and  
81 engineering, general and specialty building trades, and supply chains of material vendors and specialty  
82 suppliers.

83 In this paper, through a review of two case studies, we explore how construction projects deal with  
84 complexity through the lens of change management processes. We examine the effects of this  
85 management and its impact on project schedule and cost and its ability to recognize and deploy the  
86 human evolutionary need to build.

87 Case Study One - reviews of the project's existing, top-down, centralized system for project change  
88 orders (CO), and -

89 Case Study Two -reviews the results of an innovative bottom-up decentralized, system which was  
90 implemented to correct the failures identified in Case Study One.

91 This paper is organized as follows-

Using Time and Material (T&M) to Develop and Guide Holons in a Design and Construction Project -  
The results of Two Case Studies.  
Cliff Moser

- 92 • Introduction
- 93 • Case Study One – review of the existing system of project change controls.
- 94 • Literature Review – where we review the existing systems of construction change management
- 95 controls, holons and holonic teams, and human niche-construction
- 96 • Research Question – Outline of the question identified from Case Study One, and proposed
- 97 solution
- 98 • Methodology – How we proposed to implement the solution
- 99 • Case Study Two – Implementation of the Methodology
- 100 • Analysis – Results of the Implementation
- 101 • Contribution – How this work can add to the body of knowledge for managing project change
- 102 • Conclusion and next steps.

103

104 In this Introduction, we review the fundamental concepts of traditional change management controls  
105 for design and construction projects.

106 Then, we present the results from Case Study One – a results of a review of the existing CO processes for  
107 a large, long duration hospital project in California.

108 Then, in the Literature Review, we present -

- 109 1. A review of traditional change management project controls for construction projects,
- 110 2. How construction projects evolve into Complex Adaptive Systems (CAS)
- 111 3. The emergence of Holons in CAS
- 112 4. And the driving force of Human Niche-Construction in creating built environments

Using Time and Material (T&M) to Develop and Guide Holons in a Design and Construction Project -  
The results of Two Case Studies.

Cliff Moser

113 Then, as a result of that review, we outline the Research Question – “Do traditional construction project  
114 controls thwart the human need to build, creating an industry that is inefficient and unproductive?”

115 Then, we identify the Methodology we used to test the Research Question.

116 Then, in Part Two, we outline the deployment of that Methodology, delineating, with metrics, the  
117 results from Case Study Two.

118 Then we Analyze the results from the deployment of the Methodology.

119 Then, we outline the Contribution of this Case Study to the body of knowledge on managing design and  
120 construction projects.

121 Then, in the conclusion, we outline the next steps for our research.

122

123 Introduction – Fundamental Concepts of Design and Construction Project Change.

124 Change Orders (COs) [7] exist to manage the dynamic nature of design and construction projects. For  
125 example, change may be a result of incomplete design information, deferred work, owner changes,  
126 unforeseen site conditions, or other issues.

127 Design and construction contracts are developed not only to plan and build a project but to manage  
128 project risk. Contracts are written to mitigate and assign scope, cost, and schedule risk, with “changes in  
129 the work” clauses that define the processes for documenting and submitting COs [8].

130 Most contracts follow the Design-Bid-Build (DBB) [9] methodology, where the project owner, referenced  
131 in this paper as the Owner, holds separate contracts with the design and building teams. The design  
132 team, referenced in this paper as the Architect of Record (AOR), has contract liability for producing

Using Time and Material (T&M) to Develop and Guide Holons in a Design and Construction Project -  
The results of Two Case Studies.

Cliff Moser

133 design documents for a building permit, issued by the Authority Having Jurisdiction (AHJ). The Owner  
134 then enters a separate contract with the builder, or General Contractor, referenced in this paper as GC,  
135 to build the project according to their experience and understanding of the AOR's design documents.  
136 The GC typically subcontracts to multiple specialty trade builders, identified as Trades, who assist the GC  
137 in building the project.

138 This contracting process dictates the legal communication between the Owner, AOR, and GC/Trade  
139 teams during design and construction. Change is typically initiated through Requests for Information  
140 (RFI) [10]. Each party controls its RFI process. Construction RFIs (CRFI) are written by the GC/Trades and  
141 submitted to the Owner. AOR RFIs (ARFI) are written by the AOR and submitted to the Owner. The  
142 Owner may also write ORFIs to initiate change to the work.

143 CO management.

144 For a GC/Trades change, the Owner will issue a CO to the GC for review and pricing, who returns with an  
145 estimated cost and schedule impact for the Owner's review. Once approved, the CO will be incorporated  
146 into the permitted project documents, and the GC will begin the work.

147 CO review and negotiation steps may develop between the Owner and GC/Trades, before CO approval.

148 As a result, Reimbursable time and materials (T&M) [11] may also be used to remedy COs under review.

149 T&M enables the GC/Trades to begin the disputed work and submit labor timesheets and material  
150 invoices tracking the work as it is completed. However, T&M is typically not used for an entire project or  
151 even large areas where there is a mix of multiple trades and potential overlap between existing bid  
152 contract work and the CO work.

153

Using Time and Material (T&M) to Develop and Guide Holons in a Design and Construction Project -  
The results of Two Case Studies.  
Cliff Moser

154 Results of Case Study One

155 Case Study One lists the results of four years of CO workflows on a large, multi-year California hospital  
156 project using traditional CO processes. The project's construction contract was a Guaranteed Maximum  
157 Price (GMP) [12] valued at \$1.2b. A GMP contract is a variation of the traditional DBB contract. Like a  
158 DBB, the GC self-performs a percentage of work while managing multiple specialty Trades such as  
159 electrical, plumbing, drywall, etc., who do most of the project scope. Before the project begins  
160 construction, the GC and Owner agree to a GMP cost and schedule. To help manage a GMP contract, the  
161 Owner may create another separate contract with a Construction Manager (CM) [13] or rely on internal  
162 staff to perform CM responsibilities. On this project, the Owner developed its own CM staff for  
163 construction review processes. In this paper, they are referenced as CM.

164 The AHJ reviewing the progress of construction against the permitted design documents is referenced as  
165 the inspector of record (IOR) [14], who, working for the Owner, performs inspections and signs-off the  
166 project's completed work. The IOR uses the AOR's permitted documents (including incorporated COs) to  
167 perform their inspections.

168 This CO review process is shown in **Figure 1**. The AOR provides design changes to the CM; the CM  
169 completes an internal estimate of the cost and time impact, approves those changes, and submits the  
170 changes to the GC for pricing. The GC sends the approved changes to their Trades for pricing. The Trades  
171 return their estimated cost and time impact, back to the GC, who, in turn, reviews, approves, adds their  
172 markup, and submits the total change impact back to the CM, who reviews,  
173 approves/rejects/negotiates, and sends to the Owner for inclusion in the Contract.

174 *Figure 1*

175

The results of Two Case Studies.  
Cliff Moser

176 Year Four of Nine

177 We began our involvement in the project to assess the impact of the CO process. Our review found that  
178 four years into the project, there were unreconciled COs totaling \$150m (see table 1). Our breakdown  
179 found that the disputes were categorized as follows-

- 180 1. Contract/CO overlap. In this dispute, the CO was rejected because the CM disagreed with the  
181 scope, identifying the majority was already captured in the GMP.
- 182 2. Scope disagreement. CO rejected because GC/Trades and CM disagreed on scope impact.
- 183 3. Re-coordination. CO rejected as CM believed re-coordination was “means and methods”,  
184 already included in GMP.

185 Time is more than money.

186 The monthly progress payment process became the focus of our next CO review metric. Monthly  
187 progress payments are based on the GC/Trades’ completion of work shown against their submitted  
188 schedule of values (SOV) [15]. The SOV is submitted at the beginning of the project and delineates the  
189 total costs for the Trade and self-performed work by the GC. COs cost and schedule impacts are added  
190 to the SOV. Monthly progress invoices are submitted by the GC outlining the projected percentage  
191 complete. The CM reviews the percentages against the in-field completed work, approving, or disputing  
192 the percentages. As only approved COs are included in the pay application, the GC/Trades internally  
193 tracked their ongoing disputed CO costs, adding the ongoing dispute numbers shown in table 1.

194 Additionally, the GC/Trades progress percentages were typically reduced each month by the CM team.

195 Table 2 shows the monthly reductions. These system effects were adding additional month-over-month  
196 unreconciled costs to the project.

Using Time and Material (T&M) to Develop and Guide Holons in a Design and Construction Project -  
The results of Two Case Studies.

Cliff Moser

197 Additionally, the disputes were also impacting the project's schedule. The hospital was being built to  
198 fulfill California's 2030 state seismic requirements [16]. The project had been in planning for over 15  
199 years and was a part of the system's \$5b improvement program and was planned to receive patients in  
200 late-2017 to enable the decommissioning and upgrading of existing facilities. If not complete by the  
201 beginning of 2018, the system's budgeting office predicted a shortfall of almost \$1m a day, just three  
202 years away from our start in the project. This per diem penalty included loss of revenue caused by  
203 unavailable upgrades for planned procedures only available in the new hospital. Our review shows in  
204 **figures 2-4** that CO and monthly pay application schedule impacts, if not resolved, would delay the  
205 completion of the hospital past 2020. See **figure 5**.

206 Literature Review

207 [Ordered Systems versus Complex Adaptive Systems](#)

208 Centralized controls manage ordered systems, like manufacturing. The workers, acting as agents in an  
209 ordered system, are assigned roles and activities through a centralized control system to support  
210 assembly-line precision. Managing change within an ordered system is achieved through planning and  
211 integration into the product or assembly line. The traditional CO process envisions such a process.  
212 However, large multi-year design and construction projects become dynamic systems, with agent churn,  
213 unforeseen situational change events. These activities quickly add dynamic disorder to a planned  
214 system.

215 In his 2015 book, [A Crude Look at the Whole](#) [18], John Miller writes, "agents adapt in these complex  
216 systems, probabilities govern their adaptations..." Complex systems science challenges the notion that  
217 understanding a system comes from reducing activities to their simplest components. Miller describes  
218 controlled, centralized systems as a product of modern management processes, driven by reducing

Using Time and Material (T&M) to Develop and Guide Holons in a Design and Construction Project -  
The results of Two Case Studies.

Cliff Moser

219 activities into smaller and smaller “controllable pieces,” rather than “whole-system adaption.” Accepting  
220 that complex systems are random and heterogenous allows agent understanding of loss of control.  
221 “Creating an effective decentralized decision-making process may be one of the best new old ideas to  
222 emerge from complex systems.”

223 Bernard Aritua, Nigel J. Smith, and Denise Bower define a complex system as one which has -

- 224 1. Large numbers of dynamically interacting agents and elements.
- 225 2. System openness, with undefined boundaries.
- 226 3. Elements in the system are unaware of the entirety of the system’s behavior and respond only  
227 to what is available or known locally.
- 228 4. System history. Memories and actions are shared and replicated between agents and activities.
- 229 5. Agent churn. Agents are added and subtracted. As a result, existing agents become engaged and  
230 disengaged throughout the system’s life cycle.
- 231 6. The system relies on agent social dependence and feedback loops reinforced through human  
232 interaction and behavior. [17]

233 This is further delineated at an organizational level by Middleton and Kelly [18], with a comparison of the  
234 similarities of a design and construction project and a CAS shown in Table 3.

235 *Table 3 - Characteristics of a CAS and Design and Construction Projects (Middleton-Kelly, 2003)*

236

237 As the front-line staff adapts to the system’s randomness, they deploy distributed and situational  
238 decision-making, creating additional misalignment and disorder [19]. These front-line agents begin  
239 negotiating as individuals and groups, rather than relying centralized controls.

240 [Guiding a Complex Adaptive System](#)

241 These new project teams must choose the requirements of top-down controls or accepting the localized  
242 project needs. This results in behavior that Liang, An, Yang, and Huang describe in *Contrarian Behavior in*  
243 *a Complex Adaptive Systems* [20] where agents-

- 244 1. **defy** existing top-down controls in a **positive** response to **local project needs**. Or-
- 245 2. **adhere** to existing project controls in a **negative** response to **local project needs**.

246 Management may recognize this behavior, adjust their controls to reward and reinforce agent adaption.  
247 Rammel et al. [21] recommend developing processes that allow the system and its agents to emerge  
248 and co-evolve with the project's needs.

249 [Lean Construction and Last Planner Systems.](#)

250 Organizations develop tools to manage disorder in ordered systems, creating a *flexible* workforce  
251 through cross-training to adapt to an ordered system. For example, Toyota developed the Toyota  
252 Production System (TPS) [22], redesigning factory assembly lines to do this. TPS has been replicated in  
253 numerous manufacturing systems and is now known as Lean [23].

254 However, in design and construction projects, it is difficult to cross-train the front-line workers. The  
255 plumbers cannot be electricians, electricians cannot be framers and drywallers, and the flooring trades  
256 cannot perform framing and drywall work. Furthermore, the professional liability requirements of the  
257 AOR and GC/Trades require separation of roles [24]. Workers are the inflexible agent inputs, requiring  
258 the system and project to become flexible.

259 The Lean Construction Institute (LCI) [25] created The Last Planner System® (LPS) [26], to address this  
260 inflexibility, assigning the role of *Last-Planner* to superintendents or job captains. These *last planners* are  
261 empowered to revise schedule to support the front-line worker's needs. LPS utilizes pull planning

Using Time and Material (T&M) to Develop and Guide Holons in a Design and Construction Project -  
The results of Two Case Studies.

Cliff Moser

262 processes [27], which plan backward from a task or project's scheduled completion date, and "pull" all  
263 activities and tasks to meet the end date, developing bi-directional feedback loops, identifying the tasks  
264 and handoffs between all agents in the plan -AOR, GC/Trades, IORs. This plan is flexible and adaptable,  
265 continuously updated throughout the project lifecycle, utilizing daily check-ins and lookaheads, until the  
266 planned activity (and project) is completed. The LPS implements agent social pressure, utilizing team  
267 commitments as promises measured by *Percent Planned Complete* (PPC) [28], which calculate the  
268 "*promised to complete work.*"

### 269 Holonic Emergence and Self-Organization

270 As the front-line agents adapt to their individual, group, and project needs, they must still attend to  
271 their incumbent leadership domain requirements. This causes the agents to bifurcate into two roles -  
272 one where they serve the project and their team members, and another as they maintain their  
273 organizational reporting requirements. This dual adaptive and reporting behavior is expected by agents  
274 participating in a CAS and described as *Holons*.

275 Holons, delineated by Author Koestler in his book Ghost in the Machine [29], are sagents who emerge  
276 and self-organize in an adaptive response to required project tasks. Holons fulfill and support their  
277 individual and group needs while maintaining their larger organizational roles.

278 Naticchia, Carbonari, and Vaccanni [30] describe project-based holonic control systems, where Holons  
279 are allowed to independently design and manage project activities. Zekavat, Moon, and Bernold  
280 describe similar systems [31], which where Holons self-design and guide project management systems.

281 Valckenaers and Van Brussel describe manufacturing systems that utilize the adaptive ability of holonic  
282 emergence and behavior to control system processes[32]. Holons are key to operating Industry 4.0 [33]  
283 enabled systems. In these systems, holons are independent, autonomous units, given agency to plan

Using Time and Material (T&M) to Develop and Guide Holons in a Design and Construction Project -  
The results of Two Case Studies.

Cliff Moser

284 and act on projects with minimal interference, entrusted to adjust as necessary to guide the project's  
285 requirements.

286 [Co-Location and Social Network Systems](#)

287 Social network systems (SNS) [34] also guide Holons. As more agents join the project, they become  
288 Holons - 1) cooperating to fulfill the project needs and 2) balancing those needs with their leadership  
289 and contract requirements.

290 Co-location [32] promotes the collaborative social networks on a project. A Co-located physical space is  
291 often called the Big-Room [35], and allows the project's Holons as shared space to work together. The  
292 Big-Room's activities typically begin during pre-construction and continue into construction and project  
293 close-out. The big room becomes an Oobeya space [36] learning platform where the Owner, AOR and  
294 CM, GC/Trades and IOR share their domain and project knowledge. A Big-Room/Oobeya exists  
295 throughout the construction lifecycle and can also be used to help the Owner's Facilities team  
296 understand how the building they will be receiving will function and be managed.

297 Human Niche-Constructors and Temporary Work

298 Design and construction Holons are also engaging in human niche-constructor (HNC) [37] behavior,  
299 responding to their evolutionary need to socially band together to modify nature through intentionally  
300 constructed environments. The activities of HNC have created distributed and diverse human niches  
301 around the planet.

## 302 Research Question

### 303 Hypothesis

304 As a result of the Case Study One research and literature review describing construction projects as  
305 complex adaptive systems and the emergence of socially connected holonic teams, who need to build as  
306 Niche-Constructors, we outline the Research Question.

307 Construction projects become CAS that cannot be managed with traditional top-down, centralized  
308 project controls. The project's agents become Holons with agency to understand, adapt and respond to  
309 the project's requirements.

310 Do traditional construction project controls thwart the human need to build, creating an industry that is  
311 inefficient and unproductive?"

### 312 Methodology

#### 313 Building a Holonic Support Framework

314 Where we identify the methodology used to test the Research Question.

315 As a member of the CM team, we developed a root cause review of the ongoing CO negotiation and  
316 progress payment disputes. In our first meetings with the GC, we were shown \$44.4 million in disputed  
317 costs and 114 days of disputed schedule delays (See Table 2)

318 *Table 1.*

### 319 Reimbursable Time and Materials

320 We would begin the process by modifying the project's existing Time and Material (T&M) system as  
321 follows-

Using Time and Material (T&M) to Develop and Guide Holons in a Design and Construction Project -  
The results of Two Case Studies.

Cliff Moser

- 322 1. Begin in the back office of the project, the onsite trailers, which would utilize the project's  
323 existing Big Room/Oobeya team engagement.
- 324 2. Once a CO was coordinated and detailed in the shared construction models, the CO would move  
325 into the field for installation and inspection.
- 326 3. We agreed to register every CO with a unique Cost Issue (CI) number, enabling all team  
327 members, not just the CG and Trades, but also the AOR, IORs, and our CM team, to charge to  
328 the CI. This would allow a capturing of all costs to capture the entirety of the impact of the CO.  
329 Progress payments would be made throughout the CO cycle, using the CI unique identifier.
- 330 4. All work would be validated through observations, model review during design and  
331 coordination, and infield during installation and inspection. This would enable a feedback loop  
332 with end-to-end tracking that would validate the *Total Cost* of the CO, which could help  
333 reconcile the disputed COs.

334 The system requires streamlining the existing GC, Trade, and AOR project billing and account payables  
335 systems. For the T&M CO program, a centralized tracking system was created to enable the real-time  
336 collection of labor and materials as the work was being completed.

337

## 338 Part 2

339 Where we outline the deployment of that methodology. We include metrics, what was deployed, how it  
340 was deployed, and what happened.

## 341 Don't call us Holons

342 Some notes on terminology.

Using Time and Material (T&M) to Develop and Guide Holons in a Design and Construction Project -  
The results of Two Case Studies.

Cliff Moser

343 While applying the methodology, we were conscious of the Hawthorne Effect [38], which describes the  
344 activities of agents aware of their participation in a study modify their behavior accordingly. Therefore,  
345 we continued to use the construction industry terms for the adapting processes.

346 1. Workers/Crews, not Holons/Holonic Teams. When we started the project, we recognized that  
347 the individual front-line agents were already exhibiting holonic behavior by gathering into  
348 temporary groups for coordination and installation tasks. Rather than calling these groups out  
349 as holons, we maintained the use of existing construction terminology referencing the  
350 workers as Foreman, Journeyman, Apprentice, and Laborer [39]. These experience-related  
351 roles did not determine the roles the agents played as holons. A Foreman or Journeyman  
352 could, and did, perform similar roles as members of the holonic teams shown below-

- 353 a. Coordinating Holons – Holonic team of the CM and GC/Trade PMs and Foremen to  
354 ensure work was identified, tracked, and paid.
- 355 b. Scheduling Holons – GC/Trade PMs and Foremen, Identify the work that needs to be  
356 done, and schedule with the workers/crew, based on Last Planner roles.
- 357 c. Worker Holons - Front-line staff of workers and crew-including onsite AOR staff for  
358 decision-making. This staff performed design sketches, coordination, and construction.
- 359 d. Inspection Holons – GC/Trade QC PMs and IORs Inspecting and approving the work.
- 360 e. Payment Holons – CM/GC/Trade PMs, ensure tickets are signed, turned in, and paid

361 2. The Big-Room, not Oobeya Space. Our field trailers functioned as co-located offices and  
362 meeting rooms for all team members. This space included the necessary internet and servers,  
363 monitors, meeting rooms, etc., and offices or hoteling space. Other project team members  
364 came into the trailers for coordination and OAC [40] meetings. We formalized the learning  
365 occurring during the CO/CO review meetings. But did not call the space an Oobeya.

366

### 367 [Formalizing Change Review through a Triage Platform.](#)

#### 368 RFI Triage Meetings

369 Triage [41] describes the sorting of tasks according to urgency. We used the term to sort RFIs by  
370 urgency, creating a weekly Triage T&M meeting (See Figure x), during which each closed RFI would be  
371 “Triaged”, with the GC/Trades, CM, and AOR reviewing the project impact. Each impact would be  
372 reviewed, negotiated, coordinated, and approved during the meeting. A CI was created, schedule  
373 reviewed, and the Trades would continue the work they started with the initial review of the RFI,  
374 continuing coordination in the trailer and onto installation in the field.

375 *Figure x*

#### 376 Inspection Software

377 We augmented the project’s existing in-field inspection cloud-based software application, which also  
378 housed the project’s floor plans and inspection requests. We added the approved CO/RFI documents,  
379 and CI numbers, and time-keeping module, allowing each holon to use the system to post their hours  
380 and material costs to the CI number.

### 381 [Integrating Design Holons into the in-field teams](#)

382 The AOR and their teams are required throughout the construction phase of a project, typically already  
383 charging their time to construction administration T&M [42]. We added them to the inspection time-  
384 keeping program and began tracking their time to a CI number as well.

Using Time and Material (T&M) to Develop and Guide Holons in a Design and Construction Project -  
The results of Two Case Studies.

Cliff Moser

385 Promoting social networks for the project's niche-constructors

386 Our research question pursued a methodology that would recognize and support workers as Holons, but  
387 also their roles as niche constructors, recognizing and rewarding their role as creators of new built  
388 environments. In this role they were more than builders, they were delegates for the project and the  
389 current and future users, representing our need to build, actively shaping an environment in which all  
390 humans participate as users.

391 Furthermore, due to the system's dynamics [43], at work within the CAS, the entire regional healthcare  
392 system and supply chain would be affected by their efforts. As happens in all dynamic CAS, our holons  
393 were building more than just a hospital; they were facilitating changes to the delivery of healthcare  
394 services. This was reinforced in one instance, where a CM holon's daughter was planning for surgery to  
395 adjust her hip rotation due to existing titanium previously inserted in her fractured femur. The GC/Trade  
396 holons were building the OR where future operations would take place, which would enable a more  
397 precise procedure with image-guided equipment [44]. This team member reminded the teams of the  
398 value and urgency of their work.

399 The Triage T&M also rewarded the Trade, GC, and AOR domain leadership for their support for the  
400 system, ensuring that their reasonable CO estimates were 1) reviewed, 2) approved, and paid as quickly  
401 as possible.

## 402 Analyze results of the deployment of the Methodology of Case Study

### 403 Two

#### 404 Development of Holonic teams

405 We utilized and leveraged the existing holonic teams developed during the Oobeya/Big Room design-  
406 assist pre-construction efforts. These teams weren't formally recognized by the project management.  
407 The Triage T&M process produced an opportunity to acknowledge and formalize these holons. The  
408 results of Case Study Two measured against Case Study One are shown in Table x.

#### 409 *Table x*

410 The traditional CO controls processes in Case Study One were administered by the owner's CM team  
411 who were not working side by side with the front-line staff. This unequal stratification of control results  
412 from in a false "tragic necessity" [53], which is identified as a requirement to mitigate bad decision-  
413 making in large capital-intense, risk-averse projects.

414 The results of our two case studies, though limited, show this requirement to be false. The findings from  
415 case study one show that the project's top-down controls for the change request (CO) process had a  
416 continuous building negative effect on project productivity and efficiency, adding multiple delay and  
417 cost impacts. Traditional project controls "regard cost overruns and delays as **types** of risks";  
418 however, "both cost overruns and delays are **consequences** of other risks which occur because of  
419 other internal or external factors" [46].

420 These factors included three items-

- 421 1) the multiple and recurring layers of review,
- 422 2) the ongoing disputes over proposed cost and schedule impact, and

Using Time and Material (T&M) to Develop and Guide Holons in a Design and Construction Project -  
The results of Two Case Studies.  
Cliff Moser

423 3) month-over-month reductions in pay applications.

424 With the Triage T&M program, the in-field Holons were given project agency to review and approve  
425 COs, and to develop the cost and schedule analysis, incorporate design, coordination, detailing,  
426 installation, completion, and inspection of the work.

427 [Contribution of this Case Study to the body of knowledge on design and construction](#)  
428 [controls procedures](#)

429 Front-line agents in CAS self-organize into Holons, working together to understand, shape, and guide the  
430 system. The system and holons adapt together. Traditional top-down controls inhibit this adaptation.  
431 Contracting methodologies like Design-Build and Integrated Project Delivery create less hierarchical  
432 teams, but they require fundamental contractual changes for the Owner, AOR, GC/Trades.

433 The Triage T&M program facilitated and guided the development of holons into systems of front-line  
434 design and construction support without modifying the existing contract.

435 [Conclusion and Next Steps for the Research and Methodology.](#)

436 This section presents the results of a simple but significant shift in CO processes enabled and harness  
437 self-organizing teams' creative project powers while maintaining their required responsibility to their  
438 companies and organizations.

439 The Triage T&M program's use of CIs enabled real-time tracking of team costs. As a result, several  
440 Trades incorporated their remaining contract work onto a unique T&M CI number for completion  
441 tracking, eliminating their portion of the monthly percentage pay application review. This is an  
442 opportunity to use existing T&M models for discrete tasks and break out sections of the contracted work  
443 to track as a separate T&M allowance. Since T&M processes were already used on the project for

Using Time and Material (T&M) to Develop and Guide Holons in a Design and Construction Project -  
The results of Two Case Studies.

Cliff Moser

444 discrete tasks, and the AOR was already deployed under a similar T&M program, leveraging the CI  
445 tracking feature of the Triage T&M, created a formal review process for all work.

446 And as a separately funded allowance, the Triage T&M program de-linked COs from the project's  
447 traditional controls without sacrificing contracted oversight. The payment holons ensured this through  
448 the required ticket exchanges. And once the GC/Trade leadership began receiving immediate payments  
449 from the program, the resulting cash flow enabled support for all remaining contract work to be tracked  
450 through Triage T&M, eliminating future pay application negotiations, and a validation tool to reconcile  
451 past disputed COs.

#### 452 [The Value of Incentives in Guiding a Complex Adaptive System](#)

453 We also found as Rouse writes in *Health Care as a Complex Adaptive System: Implications for Design and*  
454 *Management* [47], that “the best way to approach the management of complex adaptive systems (was  
455 by) adopting a **human-centered** perspective that addresses the abilities, limitations, and inclinations of  
456 all stakeholders,” and, “the management approach should emphasize leadership —influence rather than  
457 power.” “No one can require that stakeholders comply with organizational dictates. *They must have*  
458 *incentives to behave appropriately.*” The recognition and harnessing of holons, combined with prompt  
459 leadership affirmation of their decision-making, rewarded with payment, reinforced the *self-organizing*  
460 *and governance* of the holonic teams.

#### 461 [Developmental Niche Constructors- The Humans Need To Build](#)

462 Winston Churchill stated, “We shape our buildings, and afterward our buildings shape us,” [48],  
463 describing the co-evolution of builders and their environments. We argue that the *need to build* is a  
464 singular force driving Maslow’s foundational hierarchal needs of Physiological, Safety, Love, and  
465 Belonging [49]. Needs that can only be attained through the creation of buildings, either as consumers

Using Time and Material (T&M) to Develop and Guide Holons in a Design and Construction Project -  
The results of Two Case Studies.

Cliff Moser

466 of built environments or through interactive construction to provide for that consumption. Centralized,  
467 top-down controls inhibit this need, interrupting the cultural and social need for humans to adaptively  
468 work together in response to shape a more sustainable environment.

#### 469 [Apprenticeship and Learning](#)

470 Apprentice as teaching is key to design construction activities. As Kim Sterelny writes in [From Hominins](#)  
471 [to Humans: how Sapiens became behaviorally modern](#), [50] “apprentice learning is a very powerful  
472 mode of social learning, making possible the reliable acquisition of complex and difficult skills. It is  
473 learning by doing. But it is learning by doing in an environment seeded with informational resources.  
474 Moreover, there are many opportunities to learn by observing highly skilled practitioners. Apprentice  
475 learning identifies a form of learning that can be assembled incrementally, and once established, it  
476 brings selective cognitive and social changes that increase the reliability and reduce the cost of learning.  
477 Apprentice-based training is distributed, neutral, and inclusive.

#### 478 [Next Steps](#)

479 We showed in this paper that decentralized controls, distributed through the front-line staff, enable the  
480 development of Holons in complex systems.

481 The success of the CO Triage T&M program allowed all remaining contract work to move to the Planning  
482 and Payment platform. The traditional control systems of SOVs and Monthly Pay Applications can be  
483 disrupted through T&M tracking against the SOV, which would streamline the monthly review and  
484 approval process. The CM and AOR teams could review GC/Trades construction progress against the  
485 inspection module in real-time. While this process wouldn’t eliminate estimates and negotiations, it  
486 would automate progress tracking. Photogrammetry and Lidar [51] are now used for completion  
487 tracking and as-builts. These systems could be combined into verifying the daily progress, automatically  
488 updating the progress percentage. Sensors and other tagging devices could be used to drive the weekly

Using Time and Material (T&M) to Develop and Guide Holons in a Design and Construction Project -  
The results of Two Case Studies.

Cliff Moser

489 lookaheads for planning, facilitating the movement of holonic teams throughout the project as work and  
490 material is made available, and when to adjust the direction of movement, due to site conditions. This  
491 system would allow the teams to adapt accordingly.

492 As the Trades do most of the work, they are the most at risk for payment disputes and delays. Design  
493 and construction is a “pay when paid” [52] work environment for the Trade organizations. When a Trade  
494 invoice is submitted and approved by the GC, it rolls up into the GC’s invoice (hence the monthly pay  
495 application). After the Owner approves the invoice, it may take up to 90 days for the GC to receive  
496 payment. The GC may be allowed another 90 days to pay the Trades. The lag between completing the  
497 work and receiving payment may be up to 200 days or longer. Since the front-line staff are employees  
498 who are paid bi-weekly or monthly, whether the Trade is paid or not, the carrying burden of delayed  
499 payment rests solely on the Trades. Research shows that in 2019 the burden in the US was estimated to  
500 be \$64 billion [53]. The T&M Triage program eliminated the monthly pay app negotiation, ensuring that  
501 the GC was paid within 30 days. The GC then turned around payment to the Trades within 30 days of  
502 their receipt of payment. The 200 days were compressed down to 60 days.

503 Hesam Hamledari and the Center for Integrated Facility Engineering (CIFE) [54] have researched how  
504 blockchain and smart contracts streamline trade payments. In *Measuring the impact of blockchain and*  
505 *smart contracts on construction supply chain visibility* [55], processes are identified which create direct  
506 Trade payments. Holons could be included in this system, directly receiving payments for their  
507 completed work.

508 Distributed Autonomous Organizations (DAO) [56] could be the next step in holonic design and  
509 construction teams, facilitating the flattening of contracting, work, and payment systems. DAOs have are  
510 currently used for learning environments [57], which could be transitioned to a project’s Big-  
511 Room/Oobeya space.

Using Time and Material (T&M) to Develop and Guide Holons in a Design and Construction Project -  
The results of Two Case Studies.  
Cliff Moser

512 Conclusion

513 These two case studies demonstrated the role that traditional top-down hierarchical project controls  
514 play in exacerbating construction change management processes. We created a new change  
515 management framework within the contract through an innovative T&M platform, including new  
516 documentation, communication, and payment processes. The platform utilized existing holonic teams  
517 for distributed decision-making, expediting the time from design to the payment process and minimizing  
518 the CO negotiation process. The platform and processes were soon used to incorporate and monitor the  
519 builder's remaining contract work to assist in project completion. In addition, the platform did not  
520 require adjusting the project's existing contract terms, demonstrating that it can be applied to  
521 traditional design-bid-build design and construction projects.

522 Recognizing and rewarding holonic teams validated their role as niche-constructors, following their  
523 evolutionary need to build. creating processes and systems that acknowledge this need either as  
524 creators or consumers of built environments proves the connectedness of humans to their built  
525 environments, which can be used to generate a greater understanding of humanity's role in building.
